

Relative Calibration :

$P1 \text{ (local)} - P1 \text{ (ref)}$

$P2 \text{ (local)} - P2 \text{ (ref)}$

But what If $(P1-P2)(ref)$ is biased?

→ getting UTC(k)-GPST with P1 or P2 would be different
and

→ P3 would be affected too

We try to validate the results of calibration for P1-P2.

By the same way we look at its stability

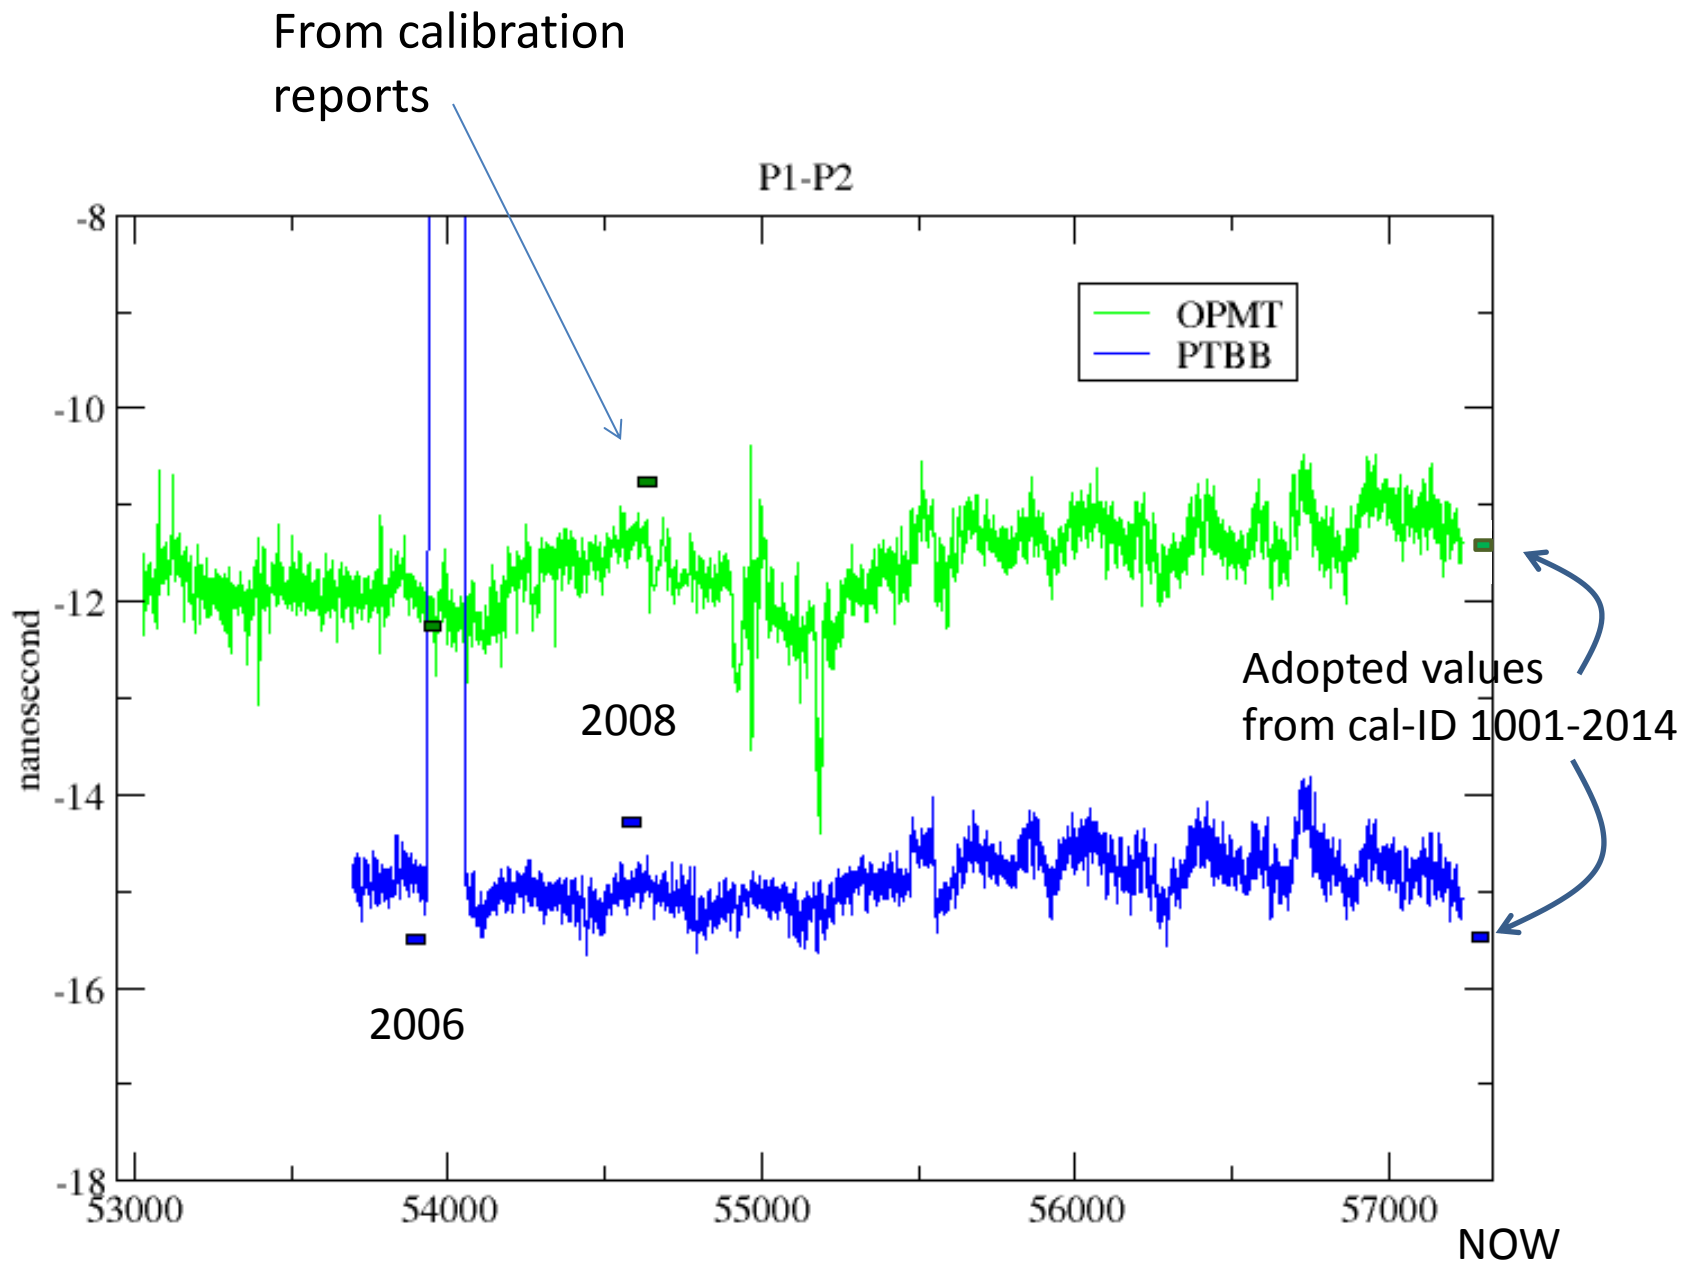

$$P_{1,2} = \rho_{1,2} - c\Delta t_{rec} + c(\Delta t_{sat} - \delta_{1,2}^{sat}) + I_{1,2} + Tr + \delta_{1,2}^{rec} + \varepsilon_{1,2}^P$$

$$(\delta_1^{rec} - \delta_2^{rec}) = P_1 - P_2 - (\rho_1 - \rho_2) + (\delta_1^{sat} - \delta_2^{sat}) - (I_1 - I_2) + \varepsilon_{1,2}^P$$

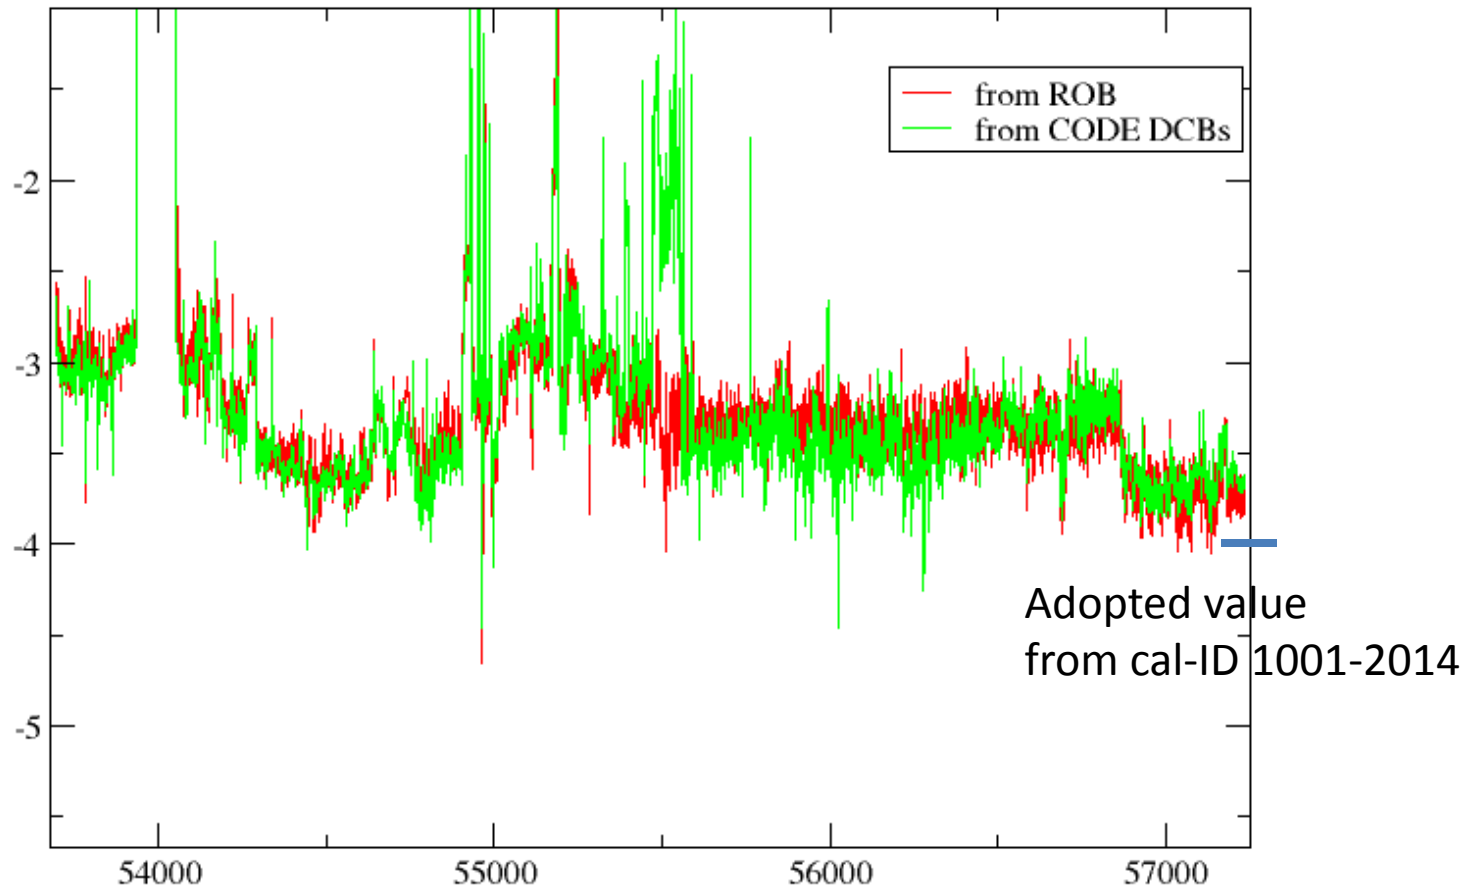

$$= \left(1 - \frac{f_1^2}{f_2^2}\right) \cdot TGD$$

$$= 40.3 \frac{f_1^2 - f_2^2}{f_1^2 f_2^2} \cdot 10^{16} \cdot TEC \cdot mapping$$

1 TECU error \rightarrow 300 ps for a sat at the zenith.
